SECTION A : 50 MARKS

BAHAGIAN A : 50 MARKAH

INSTRUCTION:

This section consists of **TWO (2)** subjective questions. Answer **ALL** questions.

ARAHAN:

Bahagian ini mengandungi ***DUA (2)*** *soalan subjektif. Jawab* ***SEMUA*** *soalan.*

QUESTION 1

SOALAN 1

CLO1 (a) Explain precipitation and interception.

Terangkan curahan dan pintasan.

[5 marks]

[*5 markah*]

CLO1 (b) The recorded inflow and outflow are 36000 m^3/h and 54000 m^3/h respectively. After 1 hour, the inflow and outflow were recorded as 15 m^3/s and 20 m^3/s. Calculate the change of storage.

Aliran masuk dan keluar masing-masing yang direkodkan ialah 36000 m^3/j dan 54000 m^3/j. Selepas 1 jam, aliran masuk dan keluar direkodkan sebagai 15 m^3/s dan 20 m^3/s. Kirakan perubahan simpanan.

[10 marks]

[*10 markah*]

CLO1 (c) Evapotranspiration is the process of the total water loss to the atmosphere from a land surface. The mean annual runoff of a 10000 x 10^6 m^2 drainage basin is 140 m^3/s. The average annual precipitation is 105 cm. Determine the losses for the area within 1 year period.

Evapotranspirasi ialah proses jumlah kehilangan air ke atmosfera dari permukaan tanah. Purata air larian tahunan bagi lembangan yang berkeluasan 10000 x 10^6 m^2 ialah 140 m^3/s. Purata curahan tahunan ialah 105 cm. Tentukan kehilangan bagi kawasan itu dalam tempoh 1 tahun.

[10 marks]

[*10 markah*]

QUESTION 2

SOALAN 2

CLO1 (a) An Intensity-Duration-Frequency (IDF) curve is a mathematical function that relates the intensity of rainfall with the duration. Explain **TWO** (**2**) the importance of IDF curve in Malaysia.

*Lengkung Keamatan-Tempoh-Kekerapan (IDF) adalah fungsi matematik yang menghubungkan antara keamatan hujan dengan tempoh masa. Terangkan **DUA (2)** kepentingan lengkung IDF di Malaysia.*

[5 marks]

[*5 markah*]

CLO1 (b) Table A2(b) shows the rainfall data for a 25 km^2 catchment area in Slim River. Calculate average rainfall data for this area by using Isohyetal method.

Jadual A2(b) menunjukkan data hujan bagi sebuah kawasan tadahan yang berkeluasan 25 km^2 di Slim River. Kirakan purata hujan bagi kawasan ini dengan menggunakan kaedah Isohyet.

Table A2(b) / *Jadual A2(b)*

Isohyetal Interval (mm) *Sela Isohyet (mm)*	Area (km^2) *Luas (km^2)*
< 10	0
10 – 20	85
20 – 30	102
30 – 40	145
40 – 50	187
50 – 60	115
60 – 70	131
70 – 80	87
> 80	111

SOALAN TAMAT

Government of Malaysia
Department of Irrigation and Drainage

Urban Stormwater Management Manual *for* Malaysia

MSMA *2nd* Edition

The criteria provided in this Chapter apply to *all* urban stormwater systems, while subsequent Chapters in the Manual give more detailed requirements for designing individual system components, quantity and quality facilities. The criteria are set based on the type of landuse, level of protection required, economy, risks of failure, public safety, ecology, aesthetics, etc. One of the most common criteria used in the facility design is the average recurrence interval (ARI), which is set based on whole life economy of the facility, the level of protection required and the hazard potentials to the downstream areas.

1.2 STORMWATER QUANTITY DESIGN CRITERIA

The minor and major systems are closely interrelated, and the design of each component must be done in conjunction with the overall stormwater management standards set by the authorities (Knox County, 2008).

Design storm ARIs to be adopted for the planning and design of minor and major storm runoff quantity systems shall be in accordance with Table 1.1. The storm runoff quantity design fundamentals are given in Chapter 2 of this Manual.

Table 1.1: Quantity Design Storm ARIs

Type of Development (See Note 1)	Minimum ARI (year) (See Note 2)	
	Minor System (See Note 3)	Major System (See Note 3)
Residential		
Bungalow and semi-detached dwellings	5	50
Link house/apartment	10	100
Commercial and business center	10	100
Industry	10	100
Sport field, park and agricultural land	2	20
Infrastructure/utility	5	100
Institutional building/complex	10	100

Notes:
1. For mixed developments, the highest of the applicable storm ARIs from the Table shall be adopted.
2. In the case where designing to the higher ARI would be impractical, the selection of appropriate ARI should be adjusted to optimise the cost to benefit ratio or social factors. If justified, a lower ARI might be adopted for the major system, with consultation and approval from the Department of Irrigation and Drainage (DID). Even if the stormwater system for the existing developed condition is designed for a lower ARI storm, sufficient land should be reserved for higher ARI flow rates, so that the system can be upgraded when the area is built up in the future.
3. All development projects shall be protected from both minor and major floods and, therefore, must have combination of minor and major systems. Habitable floor levels of the buildings (platform levels) shall be set above the 100 year ARI flood level based on the most recent data available. The drainage submission must show the minor and major system components in their drawings and plans.

The *minor system* is intended to collect, control and convey runoff from buildings, infrastructures and utilities in relatively frequent storm events (up to 10 year ARI) to minimise inconvenience and nuisance flooding. During any event larger than the minor storm ARI, the higher runoff will overspill the minor drainage components.

The *major system* is intended to safely convey and control runoff collected by the minor drainage system together with its possible overspill to the larger downstream systems and water bodies. The major system must

The drain flow time equation should be used to estimate t_d for the remaining length of the flow paths downstream. Care should be given to obtain the values of hydraulic radius and friction slope for use in the drain flow time equation. Note that recommended minimum time of concentration for a catchment is 5 minutes which applies to roof drainage.

Table 2.1: Equations to Estimate Time of Concentration (QUDM, 2007)

Travel Path	Travel Time	Remark
Overland Flow	$t_o = \frac{107.n^*.L^{1/3}}{S^{1/5}}$	t_o = Overland sheet flow travel time (minutes) L = Overland sheet flow path length (m) *for Steep Slope (>10%), L ≤ 50 m* *for Moderate Slope (<5%), L ≤ 100 m* *for Mild Slope (<1%), L ≤ 200 m* n^* = Horton's roughness value for the surface (Table 2.2) S = Slope of overland surface (%)
Curb Gutter Flow	$t_g = \frac{L}{40\sqrt{S}}$	t_g = Curb gutter flow time (minutes) L = Length of curb gutter flow (m) S = Longitudinal slope of the curb gutter (%)
Drain Flow	$t_d = \frac{n.L}{60R^{2/3}S^{1/2}}$	n = Manning's roughness coefficient (Table 2.3) R = Hydraulic radius (m) S = Friction slope (m/m) L = Length of reach (m) t_d = Travel time in the drain (minutes)

Table 2.2: Values of Horton's Roughness n^* (QUDM, 2007)

Land Surface	Horton's Roughness n^*
Paved	0.015
Bare Soil	0.0275
Poorly Grassed	0.035
Average Grassed	0.045
Densely Grassed	0.060

2.2.3 Design Rainfall Estimate

2.2.3.1 Intensity-Duration-Frequency Curves Development

The most common form of design rainfall data required for use in peak discharge estimation is from relationship represented by the intensity-duration-frequency (IDF) curves. The IDF can be developed from the historical rainfall data and they are available for most geographical areas in Malaysia.

Recognising that the rainfall data used to derive IDF are subjected to some interpolation and smoothing, it is desirable to develop IDF curves directly from local raingauge records, if these records are sufficiently long and reliable. The IDF development procedures involve the steps shown in Figure 2.1 while a typical developed curves are shown in Figure 2.2.

Table 2.3: Values of Manning's Roughness Coefficient (n) for Open Drains and Pipes (Chow, 1959; DID, 2000 and French, 1985)

Drain/Pipe	Manning Roughness n
Grassed Drain	
Short Grass Cover (< 150 mm)	0.035
Tall Grass Cover (≥ 150 mm)	0.050
Lined Drain	
Concrete	
Smooth Finish	0.015
Rough Finish	0.018
Stone Pitching	
Dressed Stone in Mortar	0.017
Random Stones in Mortar or Rubble Masonry	0.035
Rock Riprap	0.030
Brickwork	0.020
Pipe Material	
Vitrified Clay	0.012
Spun Precast Concrete	0.013
Fibre Reinforced Cement	0.013
UPVC	0.011

2.2.3.2 Empirical IDF Curves

Empirical equation can be used to minimise error in estimating the rainfall intensity values from the IDF curves. It is expressed as

$$i = \frac{\lambda T^{\kappa}}{(d + \theta)^{\eta}} \tag{2.2}$$

where,

i = Average rainfall intensity (mm/hr);

T = Average recurrence interval - ARI ($0.5 \leq T \leq 12$ month and $2 \leq T \leq 100$ year);

d = Storm duration (hours), $0.0833 \leq d \leq 72$; and

λ, κ, θ *and* η = Fitting constants dependent on the raingauge location (Table 2.B1 in Appendix 2.B).

The equation application is simple when analysis is prepared by spreadsheet. Alternatively designers can manually use the IDF curves provided in Annexure 3.

2.2.4 Temporal Patterns

It is important to emphasise that the rainfall temporal patterns are intended for use in hydrograph generation *design* storms. They should not be confused with the real rainfall data in historical storms, which is usually required to calibrate and validate hydrological and hydraulic simulation results.

The standard time intervals recommended for urban stormwater modelling are listed in Table 2.4. The design temporal patterns to be used for a set of durations are given in Appendix 2.C.

If data available, it is recommended to derive the temporal patterns using the local data following the example given in Appendix 2.D. For other durations, the temporal pattern for the nearest standard duration should be adopted. It is *NOT* correct to average the temporal patterns for different durations.

Table 2.4: Recommended Intervals for Design Rainfall Temporal Pattern

Storm Duration (minutes)	Time Interval (minutes)
Less than 60	5
60 - 120	10
121 - 360	15
Greater than 360	30

Various methods can be used to develop design rainfall temporal pattern. However, it is most important to note that design patterns are not derived from complete storms, but from intense bursts of recorded rainfall data for the selected durations. The method described herein incorporates the average variability of recorded intense rainfalls and also the most likely sequence of intensities. The highest rainfall bursts of selected design storm durations are collected from the rainfall record. It is desirable to have a large number of samples. The duration is then divided into a number of equal time intervals, as given in Table 2.4. The intervals for each rainfall burst are ranked and the average rank is determined for the intervals having same rainfall amount. The percentage of rainfall is determined for each rank for each rainfall burst, and the average percentage per rank is calculated. This procedure is then repeated for other durations. The procedure involves the steps as shown in Figure 2.3.

2.3 PEAK DISCHARGE ESTIMATION

This Section presents the methods and procedures required for runoff estimation. The recommended methods are the Rational Method and Hydrograph Methods. Each method has its own merits. *A simple Rational Hydrograph Method (RHM) is recommended for the design of small storage facilities.*

2.3.1 Rational Method

The Rational Method is the most frequently used technique for runoff peak estimation in Malaysia and many parts of the world. It gives satisfactory results for small drainage catchments and is expressed as:

$$Q = \frac{C.i.A}{360} \quad (2.3)$$

where,

- Q = Peak flow (m^3/s);
- C = Runoff coefficient (Table 2.5);
- i = Average rainfall intensity (mm/hr); and
- A = Drainage area (ha).

The primary attraction of the Rational Method has been its simplicity. However, now that computerised procedures for hydrograph generation are readily available, making computation/design by computerised method or software is also simple.

The most critical part of using the Rational Method is to make a good estimate of the runoff coefficient *C*. In general, the values of *C* depend mainly on landuse of the catchment and is very close to its imperviousness (in decimal form). The value of *C* also varies with soil type, soil moisture condition, rainfall intensity, etc. The user should evaluate the actual catchment condition for a logical value of *C* to be used. For larger area with high spatial variabilities in landuse and other parameters, this can easily be done by the use of AutoCAD, GIS or other computer softwares.

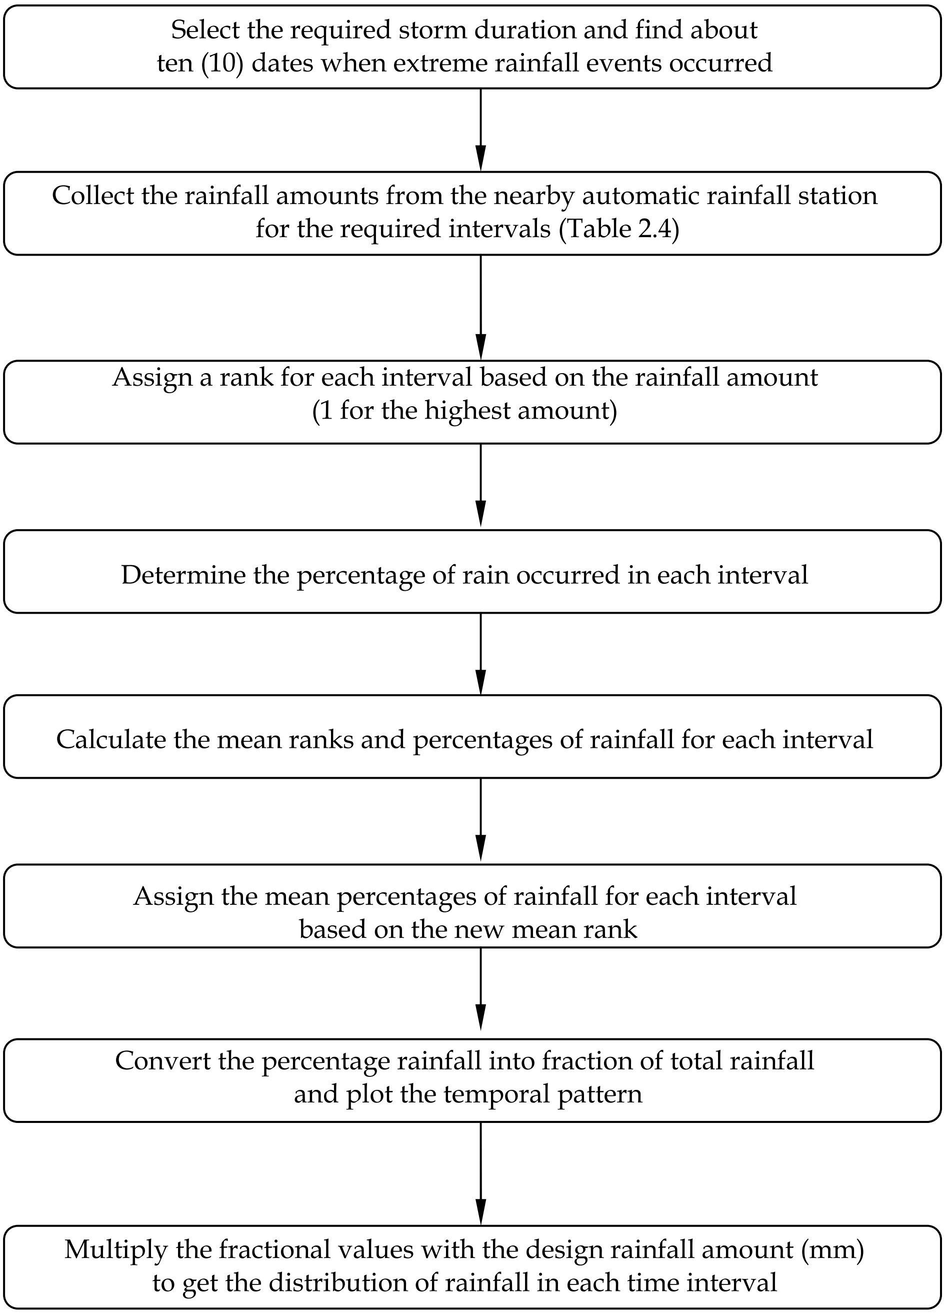

Figure 2.3: Typical Steps for the Development of Design Rainfall Temporal Pattern

2.3.1.1 Runoff Coefficient for Mixed Development

Segments of different landuse within a sub-catchment can be combined to produce an average runoff coefficient (Equation 2.4). For example, if a sub-catchment consists of segments with different landuse denoted by j = 1, 2,……, m; the average runoff coefficient is estimated, C, by:

$$C_{avg} = \frac{\sum_{j=1}^{m} C_j A_j}{\sum_{j=1}^{m} A_j} \qquad (2.4)$$

where,

C_{avg} = Average runoff coefficient;
C_j = Runoff coefficient of segment *i;*
A_j = Area of segment *i* (ha); and
m = Total number of segments.

Table 2.5: Recommended Runoff Coefficients for Various Landuses
(DID, 1980; Chow et al., 1988; QUDM, 2007 and Darwin Harbour, 2009)

Landuse	Runoff Coefficient (C)	
	For Minor System (≤10 year ARI)	For Major System (> 10 year ARI)
Residential		
Bungalow	0.65	0.70
Semi-detached Bungalow	0.70	0.75
Link and Terrace House	0.80	0.90
Flat and Apartment	0.80	0.85
Condominium	0.75	0.80
Commercial and Business Centres	0.90	0.95
Industrial	0.90	0.95
Sport Fields, Park and Agriculture	0.30	0.40
Open Spaces		
Bare Soil (No Cover)	0.50	0.60
Grass Cover	0.40	0.50
Bush Cover	0.35	0.45
Forest Cover	0.30	0.40
Roads and Highways	0.95	0.95
Water Body (Pond)		
Detention Pond (with outlet)	0.95	0.95
Retention Pond (no outlet)	0.00	0.00

Note: The runoff coefficients in this table are given as a guide for designers. The near-field runoff coefficient for any single or mixed landuse should be determined based on the imperviousness of the area.

2.3.1.2 Assumptions

Assumptions used in the Rational Method are as follows:

- The peak flow occurs when the entire catchment is contributing to the flow;
- The rainfall intensity is the uniform over the entire catchment area; and
- The rainfall intensity is uniform over a time duration equal to the time of concentration, t_c.

The Rational Method is *not recommended* for use where:

- The catchment area is greater than 80 ha (TxDOT, 2009);
- Ponding of stormwater in the catchment might affect peak discharge; and
- The design and operation of large and more costly drainage facilities are to be undertaken, particularly if they involve storage.

2.3.1.3 Calculation Steps

Steps for estimating a peak flow from a single sub-catchment for a particular ARI using the Rational Method are outlined in Figure 2.4.

APPENDIX 2.B IDF CONSTANTS

Table 2.B1: Fitting Constants for the IDF Empirical Equation for the Different Locations in Malaysia for High ARIs between 2 and 100 Year and Storm Durations from 5 Minutes to 72 Hours
